Agenda :-

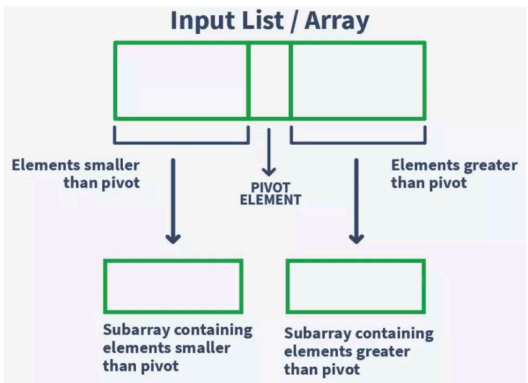
- Pivot Partition
- Quick Sort
- Comparator Problems

Ques Partition the Array.

Given an integer array, consider first element as pivot, rearrange the elements such that for all `i`:

if `A[i] < p` then it should be present on left side
if `A[i] > p` then it should be present on right side

Note: All elements are distinct



eg 56, 26, 93, 17, 77, 31, 44, 55, 20

After Partitioning

20, 55, 44, 31, 17, 26, 56, 93, 77

< 56 | 56 | > 56

Sorted Pos of 56.

eg 54, 26, 93, 17, 77, 31, 44, 55, 20

Sort the array

→ 17, 20, 26, 31, 44, 54, 55, 77 93

< 54 | > 54

T.C → O(nlogn).

Soln :-

we stop i > x.

arr[] → 54, 26, 93, 17, 77, 31, 44, 55, 20

31 | 20 | 44 | 54 | 77 | 93

swap pivot with x

31 26 20 17 44 54 77 55 93

< 54 | > 54

we stop i > x.

arr[] →

10 3 8 15 6 12 2 18 7 15 4

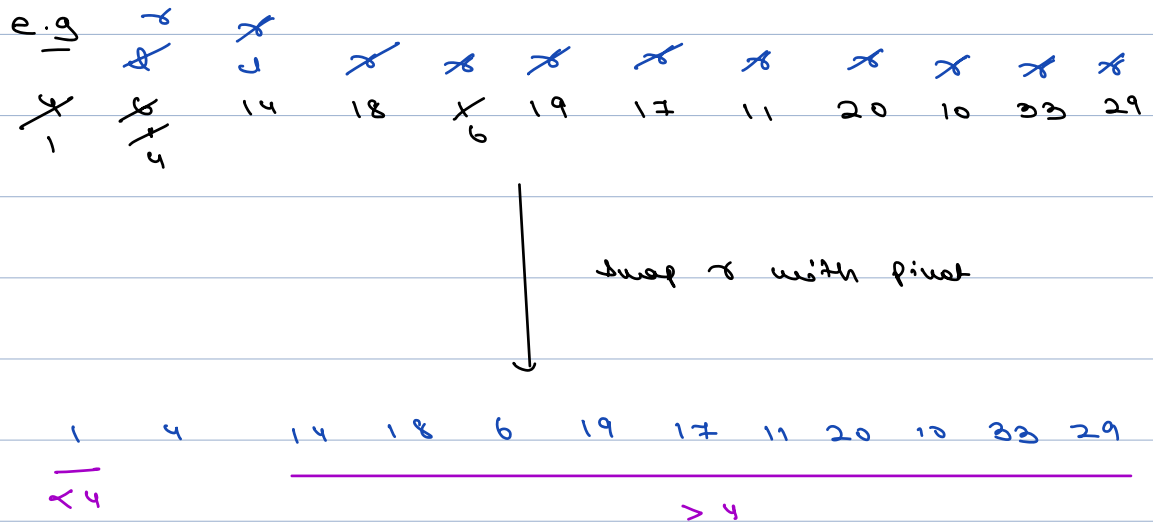
2 | 4 | 7 | 10 | 12 | 15

swap pivot with x

2 3 8 4 6 7 10 18 12 15 15

< 10 | > 10

e.g



- We begin by incrementing leftmark until we locate a value that is greater than the pivot value.
- We then decrement rightmark until we find a value that is less than the pivot value.
- At this point we have discovered two items that are out of place with respect to the eventual split point.

↓

swap these two points.

T.C → O(n), S.C → O(1)

```
Partition (arr, first, last) {
    pivotValue = arr[first];
    l = first+1;
    r = last;
    while (l <= r)
        if (arr[l] <= pivotValue)
            l++;
        else if (arr[r] > pivotValue) {
```

```
        }
        r--
    }
    else
        swap(j, r)
        j++;
        r--
    }
}
swap(arr, first, r);
return r
```

arr[] =

0	1	2	3
4	4	1	8

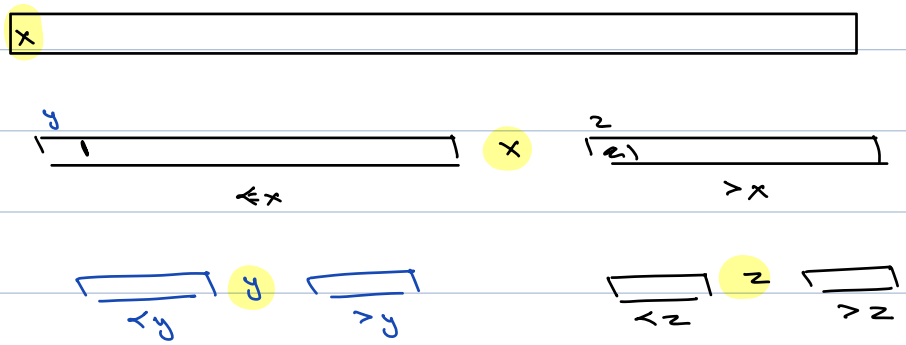
i

4 4 1 8

<= 8 | > 8

10 20 10 30 40

Quick Sort



T(n)

```
quickSort (arr, start, end) {
    if (start < end) {
        p = partition (arr, start, end)
        quickSort (arr, start, p-1);      T(n/2) →
        quickSort (arr, p+1, end);        T(n/2) →
    }
```

3

Time Complexity

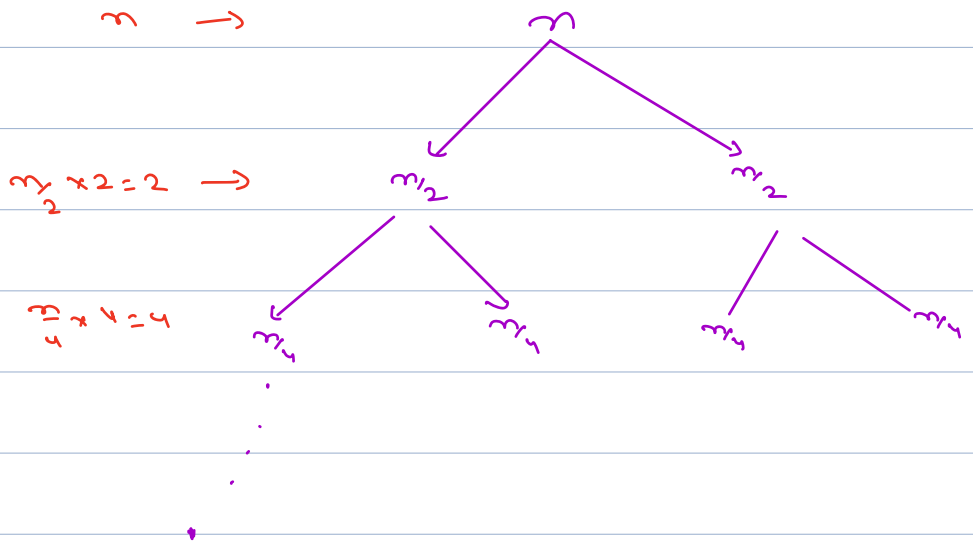
Best case.

1) when split happens equally.

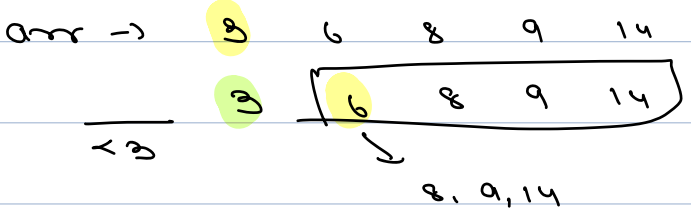
$$T(n) = 2T\left(\frac{n}{2}\right) + n$$

$$T(n) = O(n \log n)$$

S.C → O(log n)



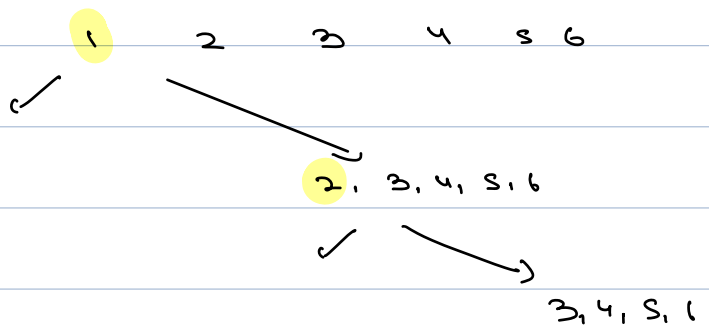
2) Worst Case :- when partition is getting skewed on one side.

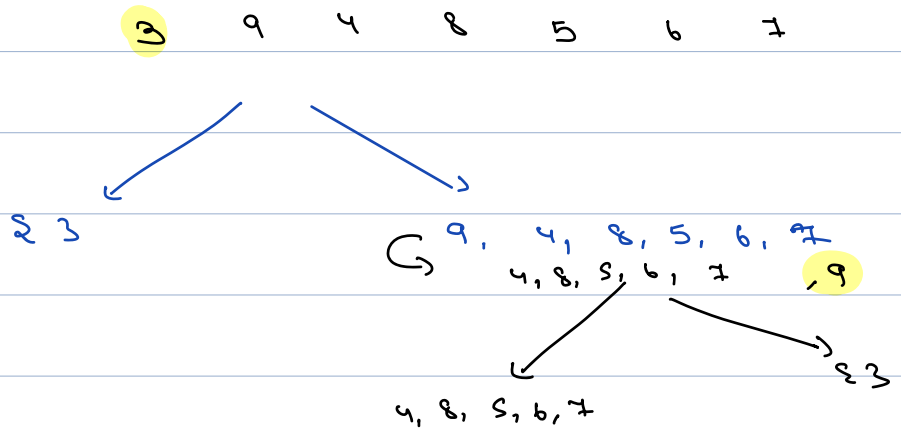


$T(n) = T(n-1) + n$

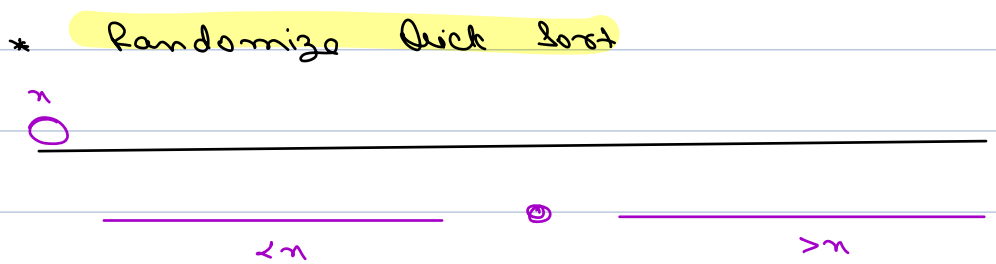
T.C → $O(n^2)$

S.C → $O(n)$



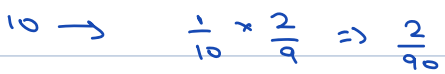


when you're getting max or min every time.



The randomised quicksort is a technique where we randomly pick the pivot element, not necessarily the first and last.

There is a random function available in all the languages, to which we can pass Array and get random index. Now, we can swap random index element with first element and execute our algorithm as it is.



Comparator

- In programming, a **comparator** is a function that compares two values and returns a result indicating whether the values are equal, less than, or greater than each other.
- The **comparator** is typically used in sorting algorithms to compare elements in a data structure and arrange them in a specified order.

For languages - **Java, Python, JS, C#, Ruby**, the following logic is followed.

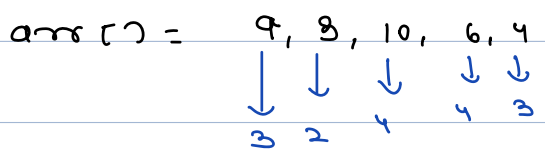
```
1. In sorted form, if first argument should come before second, -ve value is returned.
2. In sorted form, if second argument should come before first, +ve value is returned.
3. If both are same, 0 is returned.
```

For **C++**, following logic is followed.

```
1. In sorted form, if first argument should come before second, true is returned.
2. Otherwise, false is returned.
```

Ques

Given an array of size n, sort the data in ascending order of count of factors, if count of factors are equal then sort the elements on the basis of their magnitude.



→ 3, 4, 9, 6, 10

```
Collections.sort(A, new Comparator<Integer>(){
    @Override
    public int comp(Integer v1, Integer v2){
        if(factors(v1)==factors(v2)){
            if(v1<v2){
                return -1;
            }
            else if(v1>v2){
                return 1;
            }
            else{
                return 0;
            }
        }else if(factors(v1)<factors(v2)){
            return -1
        }
        else{
            return +1;
        }
    }
});
```

```
import functools

//please write the code for finding factors by yourself

def compare(v1, v2):
    if(factors(v1) == factors(v2)):
        if(v1<v2):
            return -1;
        if(v2<v1):
            return 1;
        else
            return 0;
    elif (factors(v1)<factors(v2)):
        return -1;
    else
        return 1;

class Solution:
    def solve(self, A):
        A = sorted(A, key = functools.cmp_to_key(compare))
        return A
```

```
bool compare(int val1, int val2)
{
    int cnt_x = count_factors(x);
    int cnt_y = count_factors(y);

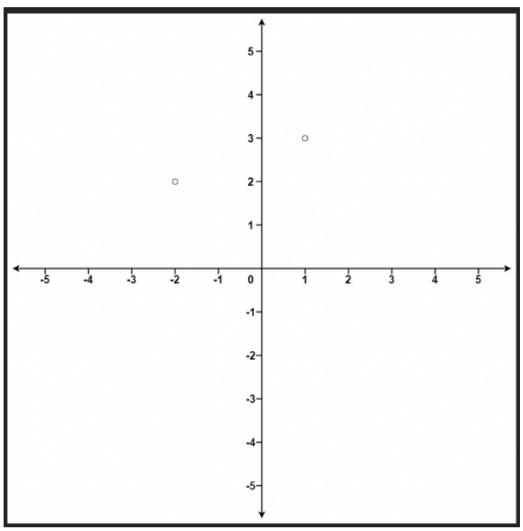
    if(factors(val1) == factors(val2))
    {
        if(val1<val2)
        {
            return true;
        }
        return false;
    }
    else if(factors(val1)<factors(val2))
    {
        return true;
    }
    return false;
}

vector<int> solve(vector<int> A) {
    sort(A.begin() , A.end() , compare);
```

Ques

Given an array of points where points[i] = [xi, yi] represents a point on the X-Y plane and an integer k, return the B closest points to the origin (0, 0).

The distance between two points on the X-Y plane is the Euclidean distance (i.e., $\sqrt{(x1 - x2)^2 + (y1 - y2)^2}$).



(x, y)

$\sqrt{x^2+y^2}$

e.g 1) pts [[1,3],[-2,2]], B = 1

$\sqrt{1^2+3^2}$ = $\sqrt{10}$

$\sqrt{2^2+2^2}$ = $\sqrt{8}$

e.g 2) [[3,3], [5,-1], [-2,4]], B = 2

$\sqrt{18}$ $\sqrt{26}$ $\sqrt{20}$

array of points

↓

(x_1, y_1) (x_2, y_2)

dist1 = $x_1^2 + y_1^2$

dist2 = $x_2^2 + y_2^2$

if (dist1 < dist2) {

    return -1;

}

else {

    return 1;

}
